

E-Commerce Funnel & Conversion Performance Analysis

Tools Used: Power BI, Power Query

Objective: Analyze user behavior across the e-commerce funnel (View → Cart → Purchase), identify drop-off points, evaluate conversion rates, and provide actionable recommendations to improve conversions.

Dataset Overview: E-commerce user behavior dataset containing millions of records with event types (view, cart, purchase), product categories, brands, pricing, and timestamps.

Key Insights:

- Major drop-off occurs at the View → Cart stage (~94% users exit)
- Cart to Purchase conversion is relatively strong (~31%)
- Overall conversion rate is low (~1.68%), indicating optimization scope
- A few categories (especially electronics) drive most purchases
- Top brands like Samsung and Apple dominate sales performance

Recommendations:

- Improve product pages with better images, descriptions, and reviews
- Reduce cart abandonment using discounts and targeted offers
- Focus marketing efforts on high-performing categories and brands
- Retarget users who viewed products but did not add to cart
- Optimize pricing strategies based on user behavior trends

Conclusion: The primary bottleneck in the funnel is the View → Cart stage. While purchase intent is strong among engaged users, improving early-stage engagement can significantly boost overall conversions and revenue.
